METHODS AND COMPOSITIONS FOR MODULATING T HELPER (T$_H$) CELL DEVELOPMENT AND FUNCTION

5

RELATED APPLICATIONS

This application claims the benefit of U.S. Provisional Application No. 60/396,160, filed July 15, 2002, and U.S. Provisional Application No. 60/403,001, filed August 10   12, 2002, both of which are hereby incorporated by reference herein in their entireties.

STATEMENT AS TO FEDERALLY SPONSORED RESEARCH

This invention was made with Government support under a grant from the National 15   Institutes of Health number AI40171. The Government has certain rights in the invention.

FIELD OF THE INVENTION

The invention relates to modulators of IL-21, e.g., human IL-21, activity or levels and 20   their uses in modulating T cell, e.g., T helper (Th) cell, development and function.

BACKGROUND OF THE INVENTION

T helper (Th) subsets are distinguished by their ability to produce distinct cytokine patterns and promote specific immune responses. Th1 cells produce IFNγ and promote cell-25   mediated immunity directed towards intracellular pathogens. In contrast, Th2 cells produce the cytokines IL-4, IL-5, and IL-13, activate mast cells and eosinophils and direct B cells against extracellular pathogens. Dysregulation of Th responses can result in immunopathology in that aberrant Th1 responses can be responsible for organ-specific autoimmunity, and exaggerated Th2 responses have been associated with allergic diseases.

30   The specific cytokines produced by polarized Th cells are the primary effectors that promote differentiation of precursor Th cells, but these cells also cross-regulate the other subset's functional activity. For example IL-4 is reported to be a potent factor in promoting the

differentiation of Thp cells to Th2 effectors. In addition, IL-4 antagonizes production of IFNγ.
IL-10, another cytokine produced by Th2 cells, has also been described to inhibit Th1
development and IFNγ-induced macrophage function. Conversely, the IFNγ produced by Th1
cells amplifies Th1 development and inhibits the expansion of Th2 cells. The ability of these

5   cytokines to promote to promote development of specific Th cell subsets, while simultaneously
inhibiting the alternate developmental fate, results in a progressively polarized response.

SUMMARY OF THE INVENTION

The invention is basedin part on the discovery that the cytokine interleukin-21 (IL-21) is
expressed by a subset of T helper (Th) cells, Th2 cells, and selectively inhibits interferon γ (IFNγ)

10   levels during Th1 cell development. More specifically, it is herein shown that IL-21 is
preferentially expressed by Th2 cells generated *in vitro* and *in vivo*. In one embodiment,
exposure of developing Th cells to IL-21 specifically reduced IFNγ levels from developing Th1
cells, and thus potentiated Th2 responses. In addition, exposure of developing Th cells to IL-21
reduces Stat4 signaling, e.g., by reducing Stat4 protein and/or mRNA expression, thereby

15   modulating Th cell responsiveness to other cytokines, e.g., IL-12. Thus, methods and
compositions for modulating Th cell development and activity are disclosed. The methods and
compositions, e.g., agonists or antagonists of IL-21, described herein are useful in treating (e.g.,
curing, ameliorating, delaying or preventing the onset of, or preventing recurrence or relapse of),
or preventing, Th cell- and/or IFNγ- associated disorders or conditions, such as Th2-associated

20   disorders, e.g., asthma, allergy, and disorders associated with antibody components (e.g.,
rheumatoid arthritis, multiple sclerosis and lupus); and Th1-associated disorders, e.g.,
autoimmune disorders (e.g., multiple sclerosis, rheumatoid arthritis, type I diabetes, Crohn's
disease, psoriasis and myasthenia gravis, among others).

25   In one aspect, the invention features a method for inhibiting, e.g., reducing or eliminating,
interferon gamma (IFNγ) levels in a T cell or cell population. The method provides, for example,
inhibiting IFNγ activity, expression, secretion, or processing in a T cell, e.g., a T cell precursor
cell (a Thp cell), or a Th1 cell (e.g., a differentiating Th1 cell or an effector Th cell), or in a T cell
population thereof. The method includes contacting the T cell or cell population with an IL-21

agonist in an amount sufficient to inhibit IFNγ (e.g., reduce or eliminate) in the T cell or cell population, such that the agonist is an IL-21 polypeptide comprising an amino acid sequence which is at least 85% identical to SEQ ID NO: 2, and which is capable of binding to an IL-21R. In some embodiments, the method further includes identifying a T cell or cell population in

5 which inhibition of IFNγ levels is desired.

In another aspect, the invention features a method for promoting differentiation of a Th precursor (Thp) cell or cell population into a Th2 cell or cell population. In one embodiment, the method includes contacting the Thp cell or cell population with an IL-21 agonist in amount

10 sufficient to induce differentiation of the Thp cell or cell population into a Th2 cell or cell population, and the agonist is an IL-21 polypeptide having an amino acid sequence that is at least 85% identical to SEQ ID NO: 2 and which is capable of binding to an IL-21R. In some embodiments, the methodfurther includes identifying a Thp cell or cell population in which differentiation into a Th2 cell or cell population is desired.

15

In another aspect, the invention features a method of inhibiting differentiation of a Thp cell or cell population into a Th1 cell or cell population. The method includes contacting the Thp cell or cell population with an IL-21 agonist in an amount sufficient to inhibit differentiation of the Thp cell or cell population into a Th1 cell or cell population, and the agonist is an IL-21

20 polypeptide having an amino acid sequence that is at least 85% identical to SEQ ID NO: 2 and which is capable of binding to an IL-21R. In one embodiment, this method further includes identifying a T cell population in which inhibition of differentiation of the Thp cell or cell population into a Th1 cell or cell population is desired.

25 In In some embodiments of these methods, the polypeptide includesthe amino acid sequence of SEQ ID NO:2. In some embodiments of these methods, the contacting step is carried out ex vivo, in vitro, or in vivo. A suitable subject for ex vivo or in vivo methods includes a mammalian subject, for example, a human.

In another aspect, the invention features a method for inhibiting differentiation of a Th precursor (Thp) cell or cell population into a Th2 cell or cell population. The method includes contacting the Thp cell or population with an antagonist of an interleukin-21 (IL-21)/IL-21 receptor (IL-21R) in an amount sufficient to inhibit differentiation of the Thp cell or cell

5   population into the Th2 cell population, and the antagonist is selected from the group consisting of an anti-IL21R antibody, an antigen-binding fragment of an anti-IL21R antibody and a soluble fragment of an IL-21R. The method optionally further includes identifying a T cell or cell population in which an inhibition of differentiation of Thp cell or cell population into a Th2 cell or cell population is desired. In some embodiment, the T cell population includes at least one

10   Th1 cell.

In some embodiments,he soluble fragment of an IL-21R includes an extracellular region of an IL-21 Receptor. For example, the soluble fragment can include an amino acid sequence at least 85% identical to amino acids 20 to 235 of SEQ ID NO: 4 and which is capable of binding

15   IL-21; alternatively, the soluble fragment includes amino acids 1 to 235 of SEQ ID NO:4. In related embodiments, the soluble fragment further includes an Fc fragment. In yet another embodiment, the antagonist is an anti-IL21R antibody or an antigen-binding fragment of the anti-IL21R antibody.

In yet anotherembodiment, the contacting step is carried out ex vivo, in vitro or in vivo.

20   The contacting step can be carried out in a mammalian subject, for example, the mammalian subject is a human.

In another aspect, the invention features a method for increasing interferon gamma (IFNγ) levels in a T cell or cell population. The method in one embodiment includes contacting the T

25   cell or cell population with an antagonist of an IL-21/IL-21R in an amount sufficient to increase IFNγ levels in the T cell or cell population, and the antagonist is selected from the group consisting of an anti-IL21R antibody, an antigen-binding fragment of an anti-IL21R antibody and a soluble fragment of an IL-21R. An embodiment of this method further includes identifying a T cell population in which an increase in IFNγ levels is desired.

4

In some embodiments, , the soluble fragment of an IL-21R includes an extracellular region of an IL-21 Receptor. For example, in some embodiments the soluble fragment comprises an amino acid sequence at least 85% identical to amino acids 20 to 235 of SEQ ID NO: 4 and which is capable of binding IL-21; alternatively, the soluble fragment includes amino acids 1 to 235 of SEQ ID NO:4. In related embodiments, the soluble fragment further includes an Fc fragment. In yet another embodiment, the antagonist can be an anti-IL21R antibody or an antigen-binding fragment of the anti-IL21R antibody.

In yet another related embodiment, the contacting step is carried out ex vivo, in vitro or in vivo. In some embodiments, the contacting step is performed in a mammalian subject, for example, a human.

Unless otherwise defined, all technical and scientific terms used herein have the same meaning as commonly understood by one of ordinary skill in the art to which this invention belongs. Although methods and materials similar or equivalent to those described herein can be used in the practice or testing of the invention, suitable methods and materials are described below. All publications, patent applications, patents, and other references mentioned herein are incorporated by reference in their entirety. In the case of conflict, the present specification, including definitions, will control. In addition, the materials, methods, and examples are illustrative only and not intended to be limiting.

Other features and advantages of the invention will be apparent from the following detailed description and claims.

BRIEF DESCRIPTION OF THE DRAWINGS

FIG. 1A is a representation of a Northern blot hybridization analysis examining expression of IL-21, IL-4, IFNγ, and γ actin under the various Th1 and Th2 skewing conditions described in the appended Examples.

FIG. 1B is a histogram showing the level of IL-21 mRNA relative to GAPDH mRNA in Th1 and Th2 cells following primary and secondary stimulation.

FIG. 1C is a histogram showing the level of IL-21 mRNA relative to GAPDH mRNA in primary and secondary Th1 and Th2 cells cultured in the presence or absence of IL-4 and IFNγ.

FIG. 1D is a histogram showing the level of IL-21 mRNA, IL-4 mRNA, and IFNγ mRNA relative to GAPDH mRNA in C57BL/g and BALB/c mice following infection with L. major.

5   FIG. 2A is a graphic representation of IL-4 and IL-21 cytokine production in Thp cells cultured under neutral conditions, or Th1 skewing conditions.

FIG. 2B is a histogram showing IFNγ production in IL-21 treated or mock treated Thp cells.

FIG. 3A is a graphic representation of IL-4 and IFNγ production in Thp cells cultured

10   under Th1 skewing conditions in the presence or absence of IL-22.

FIG. 3B is a graphic representation of IL-4 and IFNγ production in IL-21 treated or mock treated Thp cells treated in Th1 skewing conditions from wild-type and Stat6-/- mice.

FIG. 3C is a graphic representation of IFNγ, IL-2, and TNFα expression in IL-21 treated or mock treated Th1 cells from wild-type and Stat6-/- mice.

15   FIG. 4A is a representation of a western blot analysis of T-bet and actin protein levels in Thp cells cultured under Th1 or Th2 skewing conditions.

FIG. 4B is a histogram showing relative levels of IL-12Rβ2 mRNA relative to levels in Th1 cells.

FIG. 4C is a representation of a western blot analysis of phosphorylated Stat4, Stat4,

20   Stat1, and IL-12 polypeptide levels in Thp cells stimulated with anti-CD3 in the presence of IL-21 or mock supernatants.

FIG. 4D is a histogram showing levels of Stat4 mRNA relative to GAPDH mRNA in mock treated and IL-21 Thp cells stimulated with anti-CD3 for 48 hours in the presence of IL-21 or mock supernatants. IL-4 mRNA and IFNγ.

25   FIG. 5A is a graph showing specific swelling in TNP-KLH-immunized wild type and IL21-21R-/- mice subsequently injected with TNP-KLH or PBS.

FIG.5B is a histogram showing IFNγ production in CD4+ T cells purified from draining lymph nodes of TNP-KLH-immunized wild type and IL21-21R-/- mice restimulated by antigen.

DETAILED DESCRIPTION OF THE INVENTION

5   The invention provides methods and compositions for modulating T helper cell differentiation, development and activity by modulating the interaction between IL-21 and an IL-21 receptor. IL-21, or agents that increase IL-21 or IL-21 receptor levels in a cell population, are added to a population of T helper cells to suppress IFNγ levels in a population of Thp or Th1 cells. IL-21, or agents that increase IL-21 levels, can also be used to promote Th2 development,
10   or to potentiate Th2-mediated immune responses and/or to suppress Th1 development.

IL-21, or agents that increase IL-21 levels, can also be used to inhibit the effects of IL-12 on the T helper cell population. IL-21 or agents that increase levels of IL-21 or otherwise act as IL-21 agonists, can be used to suppress Th1 mediated diseases such as autoimmune diseases, multiple sclerosis, rheumatoid arthritis, and type I diabetes.

15   In one aspect, the invention features a method for modulating, e.g., increasing, or reducing or inhibiting, the activity or level of interferon gamma (IFNγ) in a cell, e.g., a T cell, or a cell population, e.g., a T cell population. For example, a method for modulating one or more of: IFNγ activity, expression, secretion, or processing, in a T cell, e.g., a T cell precursor cell (a Thp cell), or a Th1 cell (e.g., a differentiating Th1 cell or an effector Th cell), or a T cell
20   population thereof, is provided. The method includes:

(optionally) identifying a cell, e.g., a T cell, or a cell population, e.g., a T cell population, in which modulation (e.g., increase or reduction) of the activity or level of IFNγ is desired; and

contacting said cell or cell population with an amount of an IL-21 modulator, e.g., an IL-21 agonist or antagonist, sufficient to modulate (e.g., increase or reduce) the activity or level of
25   IFNγ in said cell or cell population.

The subject method can be used on cells in culture, e.g. *in vitro* or *ex vivo*. For example, immune cells, e.g., T cells as described herein, can be cultured *in vitro* in culture medium and the contacting step can be effected by adding one or more IL-21 modulators (e.g., an IL-21 agonist or antagonist), to the culture medium. Alternatively, the method is performed on cells (e.g.,

7

immune or T cells as described herein) present in a subject, e.g., as part of an *in vivo* (e.g., therapeutic or prophylactic) protocol.

In one embodiment, a method for reducing or inhibiting the activity or level of IFNγ in a cell, e.g., a T cell (e.g., a T cell precursor cell (a Thp cell), or a Th1 cell (e.g., a differentiating

5   Th1 cell or an effector Th cell)), or a cell population thereof is provided. The method includes (optionally) identifying a cell, e.g., a T cell, or a cell population, e.g., a T cell population, in which reduction or inhibition of the activity or level of IFNγ is desired; and contacting said cell or cell population with an amount of an IL-21 agonist, sufficient to reduce or inhibit the activity or level of IFNγ in said cell or cell population. Preferably, the Il-21 agonist specifically inhibits

10   IFNγ levels or activity, e.g., it does not reduce or inhibit the activity or level of other cytokines such IL-2 or TNFα. In one embodiment, the IL-21 agonist inhibits production of IFNγ by an IFNγ-producing cell, e.g., an IFNγ-producing Th1 cell.

In other embodiments, the invention provides a method for reducing IFNγ levels or activity in a subject. The method includes (optionally) identifying a subject in which reduction

15   of IFNγ levels or activity is desired; and administering to said subject an amount of an IL-21 agonist sufficient to reduce the levels or activity IFNγ. IFNγ can be measured using techniques known in the art, for example, intracellular cytokine staining, or an ELISA technique to determine levels in cell supernatants.

The IL-21 agonist can be an IL-21 polypeptide, a human IL-21 polypeptide, or an active

20   fragment thereof (e.g., a human IL-21 polypeptide comprising the amino acid sequence shown as SEQ ID NO:2, or encoded by a nucleotide sequence shown as SEQ ID NO:1, or a sequence substantially homologous thereto). In other embodiments, the IL-21 agonist is a fusion protein comprising an IL-21 polypeptide, e.g., human IL-21 polypeptide, or a fragment thereof fused to another polypeptide, e.g., an immunoglobulin polypeptide or a portion thereof (e.g., an Fc region

25   of an immunoglobulin polypeptide); an agonist antibody to the IL-21 receptor; or a small molecule agonist. In other embodiments, the IL-21 agonist is an agent that increases the activity or level of IL-21 by, e.g., increasing expression, processing and/or secretion of functional IL-21.

Preferably, the subject is a mammal, e.g., a human subject suffering from a disorder associated with aberrant, e.g., increased, IFNγ levels or activity, e.g., an immune disorder (e.g., a

30   T cell- mediated disorder), in an amount sufficient to ameliorate or prevent said disorder.

8

Exemplary immune disorders that can be treated (e.g., ameliorated) or prevented using agonists of IL-21 include, for example, Th1-associated disorders, such as autoimmune disorders (including, but not limited to, multiple sclerosis, rheumatoid arthritis, type 1 diabetes, inflammatory bowel disease (IBD), psoriasis and myasthenia gravis.

5   The invention additionally features a method of increasing IFNγ levels or activity in a cell, e.g., a T-cell, or a cell population, e.g., a T cell population. For example, the invention includes method for increasing IFNγ activity, expression, secretion, or processing, in a T cell, e.g., a T cell precursor cell (a Thp cell), or a Th1 cell (e.g., a differentiating Th1 cell or an effector Th cell), or a T cell population thereof. The method includes (optionally) identifying a

10   cell, e.g., a T cell, or cell population, e.g., a T cell population, in which an increase in IFNγ expression is desired; and contacting said cell with an IL-21 antagonist in an amount sufficient to inhibit binding or activity of IL-21, e.g., inhibit binding of IL-21 to an IL-21 receptor, thereby increasing IFNγ expression levels in said cell.

      The IL-21 antagonist can be, e.g., an antibody (e.g., a monoclonal or single specificity

15   antibody) to IL-21, e.g., human IL-21, or an IL-21 receptor, e.g., human IL-21 receptor polypeptide. Preferably, the antibody is a human, humanized, chimeric, or *in vitro* generated antibody to human IL-21 or human IL-21 receptor polypeptide. In other embodiments, the antagonist includes a fragment of an IL-21 polypeptide, e.g., an IL-21 receptor binding domain of an IL-21 polypeptide. Alternatively, the antagonist includes a fragment of an IL-21 receptor

20   polypeptide, e.g., an IL-21 binding domain of an IL-21 receptor polypeptide. In one embodiment, the antagonist is a fusion protein comprising the aforesaid IL-21 or Il-21 receptor polypeptides or fragments thereof fused to a second moiety, e.g., a polypeptide (e.g., an immunoglobulin chain).

      In another aspect, the invention features a method for modulating, e.g., increasing or

25   decreasing, Th2 cell activity and/or cell number. In one embodiment, a method of modulating, e.g., promoting or inhibiting, one or more of proliferation, survival and/or differentiation into (e.g., differentiation of a T cell precursor, e.g., a Th precursor (Thp), into) a Th2 cell is provided. The method includes:

      (optionally) identifying a cell, e.g., a T cell (e.g., a Thp or a Th2 cell), or a cell

30   population, where modulation of proliferation, survival and/or differentiation is desired; and

contacting said cell or cell population with an IL-21 modulator, e.g., an IL-21 agonist or antagonist, in an amount sufficient to modulate one or more of proliferation, survival and/or differentiation into (e.g., modulating differentiation of said Thp cell into a Th2 cell) a Th2 cell, thereby modulating Th2 cell activity and/or cell number.

5   The subject method can be used on cells in culture, e.g. *in vitro* or *ex vivo*. For example, immune cells, e.g., T cells as described herein, can be cultured *in vitro* in culture medium and the contacting step can be effected by adding one or more IL-21 modulators (e.g., one or more IL-21 agonists or antagonists) to the culture medium. Alternatively, the method can be performed on cells (e.g., immune or T cells as described herein) present in a subject, e.g., as part of an *in vivo*

10   (e.g., therapeutic or prophylactic) protocol.

In one embodiment, a method of reducing or inhibiting Th2 cell activity and/or cell number is provided. For example, Th2 cell activity and/or cell number can be reduced or inhibited by inhibiting or reducing one or more of proliferation, survival and/or differentiation into (e.g., differentiation of a T cell precursor, e.g., a Th precursor (Thp), into) a Th2 cell. The

15   method includes (optionally) identifying a cell, e.g., a T cell (e.g., a Thp or a Th2 cell), or a cell population, where inhibition of proliferation, survival and/or differentiation is desired; and contacting said cell or cell population with an IL-21 antagonist in an amount sufficient to inhibit or reduce one or more of proliferation, survival and/or differentiation into (e.g., inhibiting or reducing differentiation of said Thp cell into a Th2 cell) a Th2 cell, thereby inhibiting or reducing

20   Th2 cell activity and/or cell number.

The subject method can be used on cells, e.g., T cells (e.g., Thp or Th2 cells) in culture, e.g. *in vitro* or *ex vivo*.

Alternatively, the method can be performed on cells (e.g., immune or T cells as described herein) present in a subject, e.g., as part of an *in vivo* (e.g., therapeutic or prophylactic) protocol.

25   For example, the method can be used to treat or prevent a Th2-mediated disorder, e.g., asthma and allergy, in a subject. Accordingly, the invention provides a method of treating (e.g., curing, suppressing, ameliorating, delaying or preventing the onset of, or preventing recurrence or relapse of) or preventing a Th2-associated disorder in a subject. The method includes administering to a subject an IL-21 antagonist in an amount sufficient to inhibit or reduce Th2

30   cell activity and/or cell number, thereby treating or preventing a Th2-associated disorder.

Preferably, the subject is a mammal, e.g., a human suffering from a disorder associated with aberrant Th2 cell number or activity, e.g., an immune disorder (e.g., a Th2-associated disorder). The amount sufficient to inhibit or reduce the cell activity and/or number is an amount sufficient to ameliorate or prevent said disorder.

5   The IL-21 antagonist can be, e.g., an antibody (e.g., a monoclonal or single specificity antibody) to IL-21, e.g., human IL-21, or an IL-21 receptor, e.g., human IL-21 receptor polypeptide. Preferably, the antibody is a human, humanized, chimeric, or *in vitro* generated antibody to human IL-21 or human IL-21 receptor polypeptide. In other embodiments, the antagonist includes a fragment of an IL-21 polypeptide, e.g., an IL-21 receptor binding domain of

10   an IL-21 polypeptide. Alternatively, the antagonist includes a fragment of an IL-21 receptor polypeptide, e.g., an IL-21 binding domain of an IL-21 receptor polypeptide. In one embodiment, the antagonist is a fusion protein comprising the aforesaid IL-21 or Il-21 receptor polypeptides or fragments thereof fused to a second moiety, e.g., a polypeptide (e.g., an immunoglobulin chain).

15   In yet another embodiment, a method of increasing Th2 cell activity and/or cell number is provided. For example, Th2 cell activity and/or cell number can be increased by increasing one or more of proliferation, survival and/or differentiation into (e.g., differentiation of a T cell precursor, e.g., a Th precursor (Thp), into), a Th2 cell. The method includes (optionally) identifying a cell, e.g., a T cell (e.g., a Thp or a Th2 cell), or a cell population, where increased

20   proliferation, survival and/or differentiation is desired; and contacting said cell or cell population with an IL-21 agonist in an amount sufficient to increase one or more of proliferation, survival and/or differentiation into, (e.g., increase differentiation of said Thp cell into a Th2 cell) a Th2 cell, thereby increasing Th2 cell activity and/or cell number.

The IL-21 agonist can be an IL-21 polypeptide, e.g., a human IL-21 polypeptide, or an

25   active fragment thereof (e.g., a human IL-21 polypeptide comprising the amino acid sequence shown as SEQ ID NO:2, or encoded by a nucleotide sequence shown as SEQ ID NO:1, or a sequence substantially homologous thereto). In other embodiments, the IL-21 agonist is a fusion protein comprising an IL-21 polypeptide, e.g., human IL-21 polypeptide, or a fragment thereof fused to another polypeptide, e.g., an immunoglobulin polypeptide or a portion thereof (e.g., an

11

Fc region of an immunoglobulin polypeptide); an agonist antibody to the IL-21 receptor; or a small molecule agonist.

In yet another aspect, a method for modulating, e.g., increasing or decreasing, Th1 cell number and/or activity is provided. In one embodiment, a method of modulating, e.g., promoting

5   or inhibiting, one or more of proliferation, survival and/or differentiation into (e.g., differentiation of a T cell precursor, e.g., a Th precursor (Thp), into), a Th1 cell is provided. The method includes (optionally) identifying a cell, e.g., a T cell (e.g., a Thp or a Th1 cell), or a cell population, where modulation of proliferation, survival and/or differentiation is desired; and contacting said cell or cell population with an IL-21 modulator, e.g., an agonist or an antagonist,

10   in an amount sufficient to modulate one or more of proliferation, survival and/or differentiation into, (e.g., modulate differentiation of said Thp cell into a Th1 cell) a Th1 cell, thereby modulating Th1 cell activity and/or cell number.

The subject method can be used on cells in culture, e.g. *in vitro* or *ex vivo*. For example, immune cells, e.g., T cells as described herein, can be cultured *in vitro* in culture medium and the

15   contacting step can be effected by adding one or more IL-21 modulators (e.g., an IL-21 agonist or antagonist), to the culture medium. Alternatively, the method can be performed on cells (e.g., immune or T cells as described herein) present in a subject, e.g., as part of an *in vivo* (e.g., therapeutic or prophylactic) protocol.

In one embodiment, a method of reducing or inhibiting Th1 cell activity and/or cell

20   number is provided. For example, Th1 cell activity and/or cell number can be reduced or inhibited by inhibiting or reducing one or more of proliferation, survival and/or differentiation into (e.g., differentiation of a T cell precursor, e.g., a Th precursor (Thp), into), a Th1 cell. The method includes (optionally) identifying a cell, e.g., a T cell (e.g., a Thp, a cell producing IFNγ, e.g., a Th1 cell), or a cell population, where inhibition of proliferation, survival and/or

25   differentiation is desired; and contacting said cell or cell population with an IL-21 agonist in an amount sufficient to inhibit or reduce one or more of proliferation, survival and/or differentiation into, (e.g., inhibiting or reducing differentiation of said Thp cell into a Th1 cell) a Th1 cell, thereby inhibiting or reducing Th1 cell activity and/or cell number.

The subject method can be used on cells, e.g., T cells (e.g., Thp or Th2 cells) in culture,

30   e.g. *in vitro* or *ex vivo*.

Alternatively, the method can be performed on cells (e.g., immune or T cells as described herein) present in a subject, e.g., as part of an *in vivo* (e.g., therapeutic or prophylactic) protocol. For example, the method can be used to treat or prevent a Th1-mediated disorder, e.g., an autoimmune disorder (e.g., multiple sclerosis, rheumatoid arthritis, type I diabetes, Crohn's

5   disease, psoriasis and myasthenia gravis, among others), in a subject. Accordingly, the invention provides a method of treating (e.g., curing, suppressing, ameliorating, delaying or preventing the onset of, or preventing recurrence or relapse of) or preventing a Th1-associated disorder in a subject. The method include administering to a subject an IL-21 agonist in an amount sufficient to inhibit or reduce Th1 cell activity and/or cell number, thereby treating or preventing a Th1-

10   associated disorder.

     Preferably, the subject is a mammal, e.g., a human suffering from a disorder associated with aberrant Th1 cell number or activity, e.g., an immune disorder (e.g., a Th1-associated disorder as described herein). An amount sufficient to inhibit or reduce TH1 cell activity and/or cell member is an amount sufficient to ameliorate or prevent said disorder.

15   The IL-21 agonist can be an IL-21 polypeptide, e.g., a human IL-21 polypeptide, or an active fragment thereof (e.g., a human IL-21 polypeptide comprising the amino acid sequence shown as SEQ ID NO:2, or encoded by a nucleotide sequence shown as SEQ ID NO:1, or a sequence substantially homologous thereto). In other embodiments, the IL-21 agonist is a fusion protein comprising an IL-21 polypeptide, e.g., human IL-21 polypeptide, or a fragment thereof

20   fused to another polypeptide, e.g., an immunoglobulin polypeptide or a portion thereof (e.g., an Fc region of an immunoglobulin polypeptide); an agonist antibody to the IL-21 receptor; or a small molecule agonist. In other embodiments, the IL-21 agonist is an agent that increases the activity or level of IL-21 by, e.g., increasing expression, processing and/or secretion of functional IL-21.

25   In yet another embodiment, a method of increasing Th1 cell activity and/or cell number is provided. For example, Th1 cell activity and/or cell number can be increased by increasing one or more of proliferation, survival and/or differentiation into (e.g., differentiation of a T cell precursor, e.g., a Th precursor (Thp), into), a Th1 cell. The method includes:

     (optionally) identifying a cell, e.g., a T cell (e.g., a Thp or a Th1 cell), or a cell

30   population, where increased proliferation, survival and/or differentiation is desired; and

contacting said cell or cell population with an IL-21 antagonist in an amount sufficient to increase one or more of proliferation, survival and/or differentiation into, (e.g., increase differentiation of said Thp cell into a Th1 cell) a Th1 cell, thereby increasing Th1 cell activity and/or cell number.

5   The IL-21 antagonist can be, e.g., an antibody (e.g., a monoclonal or single specificity antibody) to IL-21, e.g., human IL-21, or an IL-21 receptor, e.g., human IL-21 receptor polypeptide. Preferably, the antibody is a human, humanized, chimeric, or *in vitro* generated antibody to human IL-21 or human IL-21 receptor polypeptide. In other embodiments, the antagonist includes a fragment of an IL-21 polypeptide, e.g., an IL-21 receptor binding domain of

10   an IL-21 polypeptide. Alternatively, the antagonist includes a fragment of an IL-21 receptor polypeptide, e.g., an IL-21 binding domain of an IL-21 receptor polypeptide. In one embodiment, the antagonist is a fusion protein comprising the aforesaid IL-21 or Il-21 receptor polypeptides or fragments thereof fused to a second moiety, e.g., a polypeptide (e.g., an immunoglobulin chain).

15   In yet another aspect, the invention features a method of modulating, e.g., reducing or inhibiting, or increasing, interleukin-12 (IL-12) activity or level in a cell, cell population, or a subject. The method includes:

         (optionally) identifying a cell, e.g., a T cell, cell population or subject, where modulation of IL-12 is desired; and

20   contacting said cell or cell population with, or administering to said subject, an IL-21 modulator, e.g., an agonist or an antagonist of IL-21, in an amount sufficient to modulate IL-12 activity or level in said cell, cell population, or a subject.

         In one embodiment, the activity or level of IL-12 is/are reduced by contacting said cell or cell population, or administering to said subject, an IL-21 agonist, e.g., an IL-21 agonist as

25   described herein, in an amount sufficient to reduce the activity or levels of IL-12.

         In other embodiments, the activity or level of IL-12 is/are increased by contacting said cell or cell population, or administering to said subject, an IL-21 antagonist, e.g., an IL-21 antagonist as described herein, in an amount sufficient to increase the activity or level of IL-12.

In yet another aspect, the invention features a method of modulating, e.g., reducing or inhibiting, or increasing, Stat, e.g., Stat 4, activity or level in a cell, cell population, or a subject. The method includes:

(optionally) identifying a cell, e.g., a T cell, cell population or subject, where modulation

5 of Stat activity or level is desired; and

contacting said cell or cell population with, or administering to said subject, an IL-21 modulator, e.g., an agonist or an antagonist of IL-21, in an amount sufficient to modulate Stat activity or level in said cell, cell population, or a subject.

In one embodiment, the activity or level of Stat is reduced by contacting said cell or cell

10 population, or administering to said subject, an IL-21 agonist, e.g., an IL-21 agonist as described herein, in an amount sufficient to reduce the activity or level of Stat, e.g., Stat protein or mRNA.

In other embodiments, the activity or level of Stat is increased by contacting said cell or cell population, or administering to said subject, an IL-21 antagonist, e.g., an IL-21 antagonist as described herein, in an amount sufficient to increase the activity or level of Stat, e.g., Stat protein

15 or mRNA.

In yet another aspect, the invention features a method of decreasing, inhibiting, suppressing, ameliorating, or delaying an autoimmune response (e.g., a Th1-mediated autoimmune response), in a subject. The method includes administering to a subject in need thereof an IL-21 agonist, e.g., an IL-21 agonist as described herein, in an amount sufficient to

20 decrease, inhibit, suppress, ameliorate, or delay said autoimmune response in said subject.

In yet another aspect, the invention features a method of decreasing, inhibiting, suppressing, ameliorating, or delaying a Th2-associated response (e.g., an allergic or an asthmatic response), in a subject. The method includes administering to a subject in need thereof an IL-21 antagonist, e.g., an IL-21 antagonist as described herein, in an amount sufficient to decrease,

25 inhibit, suppress, ameliorate, or delay said Th2-associated response in said subject.

In another aspect, the invention features a method of selectively identifying a Th2 cell in a cell population, e.g., a Th cell population, the method comprising determining the levels of IL-21 nucleic acid (e.g., an IL-21 gene product) or polypeptide in a test sample, e.g., a Th cell, and a reference sample, e.g., a Th1 cell; and comparing the levels of said IL-21 nucleic acid in said test

30 sample to levels of said IL-21 nucleic acid in the reference sample, e.g., the Th1 cell, wherein an

increase in levels of said IL-21 nucleic acid in said test sample relative to said reference sample indicates the test sample is a Th2 cell.

As used herein, a "Th1-associated disorder" is a disease or condition associated with aberrant, e.g., increased or decreased, Th1 cell activity (e.g., increased or decreased Th1 cell

5　responses) or number compared to a reference, e.g., a normal control. Examples of Th1-associated disorders include, e.g., autoimmune disorders (e.g., multiple sclerosis, rheumatoid arthritis, type I diabetes, Crohn's disease, psoriasis and myasthenia gravis, among others).

As used herein, a "Th2-associated disorder" is a disease or condition associated with aberrant, e.g., increased or decreased, Th2 cell activity (e.g., increased or decreased Th2 cell

10　responses) or number compared to a reference, e.g., a normal control. Examples of Th2 disorders include, e.g., asthma, allergy, and disorders associated with antibody components (e.g., rheumatoid arthritis, multiple sclerosis and lupus).

The IL-21 polypeptide used in the methods described herein can include the amino acid sequence of, e.g., a mammalian IL-21 polypeptide (such as a rodent, human, or non-human

15　primate). For example, the IL-21 polypeptide can include the amino acid sequence of a human IL-21 polypeptide. A suitable amino acid sequence is the amino acid sequence of the IL-21 polypeptide shown in SEQ ID NO:2 (below).

IL-21 and IL-21 receptor polypeptides, including nucleotide and amino acid sequences, have been described in, e.g., US Patent No. 6, 057, 128, Parrish-Novak et al., Nature 408:57-63,

20　2000; Vosshenrich et al., Curr. Biol. 11:R157-77, 2001, Asao et al., J. Immunol. 167:1-5, 2001; and Ozaki et al., Proc. Natl. Acad. Sci. USA 97:11439-44, 2000. Amino acid sequences of IL-21 polypeptides are publicly known. For example, the nucleotide sequence and amino acid sequence of a human IL-21 is available at Genbank Acc. No. X_011082. The human IL-21 nucleotide sequence disclosed in this entry is presented below:

```

The nucleic acid sequence homology may be determined as the degree of identity between two nucleotide or amino acid sequences. The homology may be determined using computer programs known in the art, such as GAP software provided in the GCG program package. See, *Needleman and Wunsch* 1970 *J Mol Biol* 48: 443-453. Using GCG GAP software with the following settings for nucleic acid sequence comparison: GAP creation penalty of 5.0 and GAP extension penalty of 0.3, the coding region of the analogous nucleic acid sequences referred to above exhibits a degree of identity preferably of at least 70%, 75%, 80%, 85%, 90%, 95%, 98%, or 99%, with the CDS (encoding) part of the DNA sequence shown in SEQ ID NO:1 or SEQ ID NO:3. Similarly the amino acid sequences referred to herein exhibit a degree of identity preferably of at least 50%, 60%, 70%, 75%, 80%, 85%, 90%, 95%, 98%, or 99%, with the amino acid sequence shown in SEQ ID NO:4, SEQ ID NO:5 or SEQ ID NO:6.

The term "sequence identity" refers to the degree to which two polynucleotide or polypeptide sequences are identical on a residue-by-residue basis over a particular region of comparison. The term "percentage of sequence identity" is calculated by comparing two optimally aligned sequences over that region of comparison, determining the number of positions at which the identical nucleic acid base (*e.g.,* A, T, C, G, U, or I, in the case of nucleic acids) occurs in both sequences to yield the number of matched positions, dividing the number of matched positions by the total number of positions in the region of comparison (*i.e.,* the window size), and multiplying the result by 100 to yield the percentage of sequence identity. The term

18

"substantial identity" as used herein denotes a characteristic of a polynucleotide sequence, wherein the polynucleotide comprises a sequence that has at least 80 percent sequence identity, preferably at least 85 percent identity and often 90 to 95 percent sequence identity, more usually at least 98 or 99 percent sequence identity as compared to a reference sequence over a

5   comparison region. The term "percentage of positive residues" is calculated by comparing two optimally aligned sequences over that region of comparison, determining the number of positions at which the identical and conservative amino acid substitutions, as defined above, occur in both sequences to yield the number of matched positions, dividing the number of matched positions by the total number of positions in the region of comparison (*i.e.,* the window size), and

10   multiplying the result by 100 to yield the percentage of positive residues.

Agents that increase IL-21 or IL-21 receptor levels in a cell or cell population can additionally include IL-21 agonists or IL-21 receptor agonists. Such agonists can be identified by identifying test compounds that exert one or more of the activities IL-21 exerts on T helper cell populations.

15   The subject can be a mammal, e.g., a human, a non-human primate, a dog, cat, cow, horse, pig or a rodent (including a rat or mouse). Any desired route of administration of IL-21 can be used. Suitable routes include intravenous (both bolus and infusion), intraperitoneal, subcutaneous or intramuscular form, all using forms well known to those of ordinary skill in the pharmaceutical arts. Injectables can be prepared in conventional forms, either as liquid solutions

20   or suspensions.

Parenteral injectable administration is generally used for subcutaneous, intramuscular or intravenous injections and infusions.

IL-21 Antagonists

25   To inhibit an IL-21 mediated T helper cell effect, an agent that blocks or otherwise inhibits the interaction of IL-21 to an IL-21 receptor can be added to a T cell or a population of T cells, e.g., T helper cells. For convenience, these inhibitors are referred to herein as "IL-21 antagonists." Examples of IL-21 antagonists include, e.g., soluble fragments of IL-21 or IL-21 receptors, fusion proteins containing these fragments, and antibodies to these fragments. IL-21

30   antagonists are useful for blocking IL-21 in Th2 mediated disease, including antibody-mediated

disease. Theses diseases include asthma, allergy, rheumatoid arthritis, multiple sclerosis, and lupus.

IL-21 and IL-21Receptor Fusion Proteins

5   IL-21, or IL-21 receptor, or active fragments of these proteins, can be fused to carrier molecules such as immunoglobulins for use in the herein described methods. For example, soluble forms of the IL-21 receptor may be fused through "linker" sequences to the Fc portion of an immunoglobulin or to the Fc portion of the immunoglobulin. Other fusions proteins, such as those with GST (*i.e.*, glutathione S-transferase), LexA, or MBP (*i.e.*, maltose binding protein),

10   may also be used.

In a further embodiment, IL-21 or IL-21 receptor fusion protein may be linked to one or more additional moieties. For example, the IL-21 or IL-21 receptor fusion protein may additionally be linked to a GST fusion protein in which the IL-21 receptor fusion protein sequences are fused to the C-terminus of the GST sequences. Such fusion proteins can facilitate

15   the purification of the IL-21 or IL-21 receptor fusion protein.

In another embodiment, the fusion protein includes a heterologous signal sequence (*i.e.*, a polypeptide sequence that is not present in a polypeptide naturally encoded by an IL-21 or IL-21 receptor nucleic acid) at its N-terminus. For example, the native IL-21 or IL-21 receptor signal sequence can be removed and replaced with a signal sequence from another protein.

20   A chimeric or fusion protein of the invention can be produced by standard recombinant DNA techniques. For example, DNA fragments coding for the different polypeptide sequences are ligated together in-frame in accordance with conventional techniques, *e.g.*, by employing blunt-ended or stagger-ended termini for ligation, restriction enzyme digestion to provide for appropriate termini, filling-in of cohesive ends as appropriate, alkaline phosphatase treatment to

25   avoid undesirable joining, and enzymatic ligation. In another embodiment, the fusion gene can be synthesized by conventional techniques including automated DNA synthesizers. Alternatively, PCR amplification of gene fragments can be carried out using anchor primers that give rise to complementary overhangs between two consecutive gene fragments that can subsequently be annealed and reamplified to generate a chimeric gene sequence (see, for

30   example, Ausubel *et al.* (eds.) CURRENT PROTOCOLS IN MOLECULAR BIOLOGY, John Wiley & Sons, 1992). Moreover, many expression vectors are commercially available that encode a

·fusion moiety (*e.g.*, an Fc region of an immunoglobulin heavy chain). An IL-21 or IL-21 receptor encoding nucleic acid can be cloned into such an expression vector such that the fusion moiety is linked in-frame to the immunoglobulin protein.

In some embodiments, the IL-21 or IL-21 receptor polypeptide moiety is provided as a

5   variant IL-21 receptor polypeptide having a mutation in the naturally-occurring IL-21 or IL-21 receptor sequence (wild type) that results in higher affinity (relative to the non-mutated sequence) binding of the altered IL-21 for an IL-21 receptor, or higher affinity (relative to the non-mutated sequence) of the altered IL-21 receptor polypeptide for IL-21.

In some embodiments, the IL-21 polypeptide or IL-21 receptor polypeptide moiety is

10   provided as a variant IL-21 or IL-21 receptor polypeptide having mutations in the naturally-occurring IL-21 or IL-21 receptor sequence (wild type) that results in an IL-21 or IL-21 receptor sequence more resistant to proteolysis (relative to the non-mutated sequence).

A signal peptide that can be included in the fusion protein is MPLLLLLLLLPSPLHP (SEQ ID NO:5). If desired, one or more amino acids can additionally be inserted between the

15   first polypeptide moiety comprising the IL-21 or IL-21 receptor moiety and the second polypeptide moiety.

The second polypeptide is preferably soluble. In some embodiments, the second polypeptide enhances the half-life, (*e.g.*, the serum half-life) of the linked polypeptide. In some embodiments, the second polypeptide includes a sequence that facilitates association of the

20   fusion polypeptide with a second IL-21 receptor polypeptide. In preferred embodiments, the second polypeptide includes at least a region of an immunoglobulin polypeptide. Immunoglobulin fusion polypeptides are known in the art and are described in *e.g.*, US Patent Nos. 5,516,964; 5,225,538; 5,428,130;5,514,582; 5,714,147; and 5,455,165.

In some embodiments, the second polypeptide comprises a full-length immunoglobulin

25   polypeptide. Alternatively, the second polypeptide comprise less than full-length immunoglobulin polypeptide, *e.g.*, a heavy chain, light chain, Fab, Fab_2, Fv, or Fc. Preferably, the second polypeptide includes the heavy chain of an immunoglobulin polypeptide. More preferably, the second polypeptide includes the Fc region of an immunoglobulin polypeptide.

In some embodiments, the second polypeptide has less effector function than the effector

30   function of a Fc region of a wild-type immunoglobulin heavy chain. Fc effector function

21

includes for example, Fc receptor binding, complement fixation and T cell depleting activity. (*see for example*, US Patent No. 6,136,310) Methods of assaying T cell depleting activity, Fc effector function, and antibody stability are known in the art. In one embodiment the second polypeptide has low or no affinity for the Fc receptor. In an alternative embodiment, the second

5   polypeptide has low or no affinity for complement protein C1q.

A preferred second polypeptide sequence includes the amino acid sequence of SEQ ID NO: 6. This sequence includes a Fc region. Underlined amino acids are those that differ from the amino acid found in the corresponding position of the wild-type immunoglobulin sequence:

```

    QGNVFSCSVMHEALHNHYTQKSLSLSPGK (SEQ ID NO:6)
```

IL-21 and IL-21 Receptor Antibodies

15   The term "antibody" as used herein refers to immunoglobulin molecules and immunologically active portions of immunoglobulin (Ig) molecules, *i.e.*, molecules that contain an antigen binding site that specifically binds (immunoreacts with) an antigen. Such antibodies include, *e.g.*, polyclonal, monoclonal, chimeric, single chain, F_{ab}, $F_{ab'}$ and $F_{(ab')2}$ fragments, and an F_{ab} expression library. In general, an antibody molecule obtained from humans relates to any

20   of the classes IgG, IgM, IgA, IgE and IgD, which differ from one another by the nature of the heavy chain present in the molecule. Certain classes have subclasses as well, such as IgG_1, IgG_2, and others. Furthermore, in humans, the light chain may be a kappa chain or a lambda chain. Reference herein to antibodies includes a reference to all such classes, subclasses and types of human antibody species. Antibodies to IL-21 or IL-21 receptor polypeptides also include

25   antibodies to fusion proteins containing IL-21 or IL-21 receptor polypeptides or fragments of IL-21 or IL-21 receptor polypeptides.

An IL-21 polypeptide or IL-21 receptor polypeptide can be used as an antigen, or a portion or fragment thereof, and additionally can be used as an immunogen to generate antibodies that immunospecifically bind the antigen, using standard techniques for polyclonal

30   and monoclonal antibody preparation. Antigenic peptide fragments of the antigen for use as immunogens include, *e.g.*, at least 7 amino acid residues of the amino acid sequence of the amino terminal region, such as an amino acid sequence shown in SEQ ID NOs:1 or 3, and encompass

an epitope thereof such that an antibody raised against the peptide forms a specific immune complex with the full length protein or with any fragment that contains the epitope. Preferably, the antigenic peptide comprises at least 10 amino acid residues, or at least 15 amino acid residues, or at least 20 amino acid residues, or at least 30 amino acid residues. Preferred epitopes

5   encompassed by the antigenic peptide are regions of the protein that are located on its surface; commonly these are hydrophilic regions.

In some embodiments, at least one epitope encompassed by the antigenic peptide is a region of IL-21 or IL-21 receptor polypeptide that is located on the surface of the protein, *e.g.*, a hydrophilic region. A hydrophobicity analysis of a IL-21 or IL-21 receptor polypeptide will

10   indicate which regions of an IL-21 or IL-21 receptor protein are particularly hydrophilic and, therefore, are likely to encode surface residues useful for targeting antibody production. As a means for targeting antibody production, hydropathy plots showing regions of hydrophilicity and hydrophobicity may be generated by any method well known in the art, including, for example, the Kyte Doolittle or the Hopp Woods methods, either with or without Fourier transformation.

15   See, *e.g.*, Hopp and Woods (1981) Proc. Nat. Acad. Sci. USA 78: 3824-3828; Kyte and Doolittle (1982) J. Mol. Biol. 157: 105-142. Antibodies that are specific for one or more domains within an antigenic protein, or derivatives, fragments, analogs or homologs thereof, are also provided herein.

A protein of the invention, or a derivative, fragment, analog, homolog or ortholog thereof,

20   may be utilized as an immunogen in the generation of antibodies that immunospecifically bind these protein components.

Various procedures known within the art may be used for the production of polyclonal or monoclonal antibodies directed against a protein of the invention, or against derivatives, fragments, analogs homologs or orthologs thereof. See, for example, ANTIBODIES: A

25   LABORATORY MANUAL, Harlow and Lane (1988) Cold Spring Harbor Laboratory Press, Cold Spring Harbor, NY. Some of these antibodies are discussed below.

Polyclonal Antibodies

For the production of polyclonal antibodies, various suitable host animals (*e.g.*, rabbit,

30   goat, mouse or other mammal) may be immunized by one or more injections with the native

protein, a synthetic variant thereof, or a derivative of the foregoing. An appropriate
immunogenic preparation can contain, for example, the naturally occurring immunogenic
protein, a chemically synthesized polypeptide representing the immunogenic protein, or a
recombinantly expressed immunogenic protein. Furthermore, the protein may be conjugated to a
5   second protein known to be immunogenic in the mammal being immunized. Examples of such
immunogenic proteins include but are not limited to keyhole limpet hemocyanin, serum albumin,
bovine thyroglobulin, and soybean trypsin inhibitor.

The preparation can further include an adjuvant. Various adjuvants used to increase the
immunological response include, but are not limited to, Freund's (complete and incomplete),
10   mineral gels (*e.g.*, aluminum hydroxide), surface active substances (*e.g.*, lysolecithin, pluronic
polyols, polyanions, peptides, oil emulsions, dinitrophenol, etc.), adjuvants usable in humans
such as Bacille Calmette-Guerin and Corynebacterium parvum, or similar immunostimulatory
agents. Additional examples of adjuvants which can be employed include MPL-TDM adjuvant
(monophosphoryl Lipid A, synthetic trehalose dicorynomycolate).

15   The polyclonal antibody molecules directed against the immunogenic protein can be
isolated from the mammal (*e.g.*, from the blood) and further purified by well known techniques,
such as affinity chromatography using protein A or protein G, which provide primarily the IgG
fraction of immune serum. Subsequently, or alternatively, the specific antigen which is the target
of the immunoglobulin sought, or an epitope thereof, may be immobilized on a column to purify
20   the immune specific antibody by immunoaffinity chromatography. Purification of
immunoglobulins is discussed, for example, by Wilkinson. Wilkinson (2000) The Scientist, 14:
25-28.

Monoclonal Antibodies

The term "monoclonal antibody" (MAb) or "monoclonal antibody composition", as used herein, refers to a population of antibody molecules that contain only one molecular species of antibody molecule consisting of a unique light chain gene product and a unique heavy chain

5 gene product. In particular, the complementarity determining regions (CDRs) of the monoclonal antibody are identical in all the molecules of the population. MAbs thus contain an antigen binding site capable of immunoreacting with a particular epitope of the antigen characterized by a unique binding affinity for it.

Monoclonal antibodies can be prepared using hybridoma methods, such as those

10 described by Kohler and Milstein (1975) Nature, 256:495. In a hybridoma method, a mouse, hamster, or other appropriate host animal, is typically immunized with an immunizing agent to elicit lymphocytes that produce or are capable of producing antibodies that will specifically bind to the immunizing agent. Alternatively, the lymphocytes can be immunized *in vitro*.

The immunizing agent will typically include the protein antigen, a fragment thereof or a

15 fusion protein thereof. Generally, either peripheral blood lymphocytes are used if cells of human origin are desired, or spleen cells or lymph node cells are used if non-human mammalian sources are desired. The lymphocytes are then fused with an immortalized cell line using a suitable fusing agent, such as polyethylene glycol, to form a hybridoma cell. Goding, MONOCLONAL ANTIBODIES: PRINCIPLES AND PRACTICE, Academic Press, (1986) pp. 59-103. Immortalized cell

20 lines are usually transformed mammalian cells, particularly myeloma cells of rodent, bovine and human origin. Usually, rat or mouse myeloma cell lines are employed. The hybridoma cells can be cultured in a suitable culture medium that preferably contains one or more substances that inhibit the growth or survival of the unfused, immortalized cells. For example, if the parenteral cells lack the enzyme hypoxanthine guanine phosphoribosyl transferase (HGPRT or HPRT), the

25 culture medium for the hybridomas typically will include hypoxanthine, aminopterin, and thymidine ("HAT medium"), which substances prevent the growth of HGPRT-deficient cells.

Preferred immortalized cell lines are those that fuse efficiently, support stable high level expression of antibody by the selected antibody-producing cells, and are sensitive to a medium such as HAT medium. More preferred immortalized cell lines are murine myeloma lines, which

30 can be obtained, for instance, from the Salk Institute Cell Distribution Center, San Diego,

25

California and the American Type Culture Collection, Manassas, Virginia. Human myeloma and mouse-human heteromyeloma cell lines also have been described for the production of human monoclonal antibodies (Kozbor (1984) J. Immunol., 133:3001; Brodeur *et al.*, MONOCLONAL ANTIBODY PRODUCTION TECHNIQUES AND APPLICATIONS, Marcel Dekker, Inc., New York,

5   (1987) pp. 51-63).

The culture medium in which the hybridoma cells are cultured can then be assayed for the presence of monoclonal antibodies directed against the antigen. Preferably, the binding specificity of monoclonal antibodies produced by the hybridoma cells is determined by immunoprecipitation or by an *in vitro* binding assay, such as radioimmunoassay (RIA) or

10   enzyme-linked immunoabsorbent assay (ELISA). Such techniques and assays are known in the art. The binding affinity of the monoclonal antibody can, for example, be determined by the Scatchard analysis of Munson and Pollard (1980) Anal. Biochem., 107:220. Preferably, antibodies having a high degree of specificity and a high binding affinity for the target antigen are isolated.

15   After the desired hybridoma cells are identified, the clones can be subcloned by limiting dilution procedures and grown by standard methods. Suitable culture media for this purpose include, for example, Dulbecco's Modified Eagle's Medium and RPMI-1640 medium. Alternatively, the hybridoma cells can be grown *in vivo* as ascites in a mammal.

The monoclonal antibodies secreted by the subclones can be isolated or purified from the

20   culture medium or ascites fluid by conventional immunoglobulin purification procedures such as, for example, protein A-Sepharose, hydroxyapatite chromatography, gel electrophoresis, dialysis, or affinity chromatography.

The monoclonal antibodies can also be made by recombinant DNA methods, such as those described in U.S. Patent No. 4,816,567. DNA encoding the monoclonal antibodies of the

25   invention can be readily isolated and sequenced using conventional procedures (*e.g.*, by using oligonucleotide probes that are capable of binding specifically to genes encoding the heavy and light chains of murine antibodies). The hybridoma cells of the invention serve as a preferred source of such DNA. Once isolated, the DNA can be placed into expression vectors, which are then transfected into host cells such as simian COS cells, Chinese hamster ovary (CHO) cells, or

30   myeloma cells that do not otherwise produce immunoglobulin protein, to obtain the synthesis of

monoclonal antibodies in the recombinant host cells. The DNA also can be modified, for example, by substituting the coding sequence for human heavy and light chain constant domains in place of the homologous murine sequences (U.S. Patent No. 4,816,567; Morrison (1994) Nature 368, 812-13) or by covalently joining to the immunoglobulin coding sequence all or part

5 of the coding sequence for a non-immunoglobulin polypeptide. Such a non-immunoglobulin polypeptide can be substituted for the constant domains of an antibody of the invention, or can be substituted for the variable domains of one antigen-combining site of an antibody of the invention to create a chimeric bivalent antibody.

10 <u>Humanized Antibodies</u>

The antibodies directed against the protein antigens of the invention can further comprise humanized antibodies or human antibodies. These antibodies are suitable for administration to humans without engendering an immune response by the human against the administered immunoglobulin. Humanized forms of antibodies are chimeric immunoglobulins,

15 immunoglobulin chains or fragments thereof (such as Fv, Fab, Fab', F(ab')$_2$ or other antigen-binding subsequences of antibodies) that are principally comprised of the sequence of a human immunoglobulin, and contain minimal sequence derived from a non-human immunoglobulin. Humanization can be performed following the method of Winter and co-workers (Jones *et al.* (1986) Nature, 321:522-525; Riechmann *et al.* (1988) Nature, 332:323-327; Verhoeyen *et al.*

20 (1988) Science, 239:1534-1536), by substituting rodent CDRs or CDR sequences for the corresponding sequences of a human antibody. (See also U.S. Patent No. 5,225,539.) In some instances, Fv framework residues of the human immunoglobulin are replaced by corresponding non-human residues. Humanized antibodies can also comprise residues which are found neither in the recipient antibody nor in the imported CDR or framework sequences. In general, the

25 humanized antibody will comprise substantially all of at least one, and typically two, variable domains, in which all or substantially all of the CDR regions correspond to those of a non-human immunoglobulin and all or substantially all of the framework regions are those of a human immunoglobulin consensus sequence. The humanized antibody optimally also will comprise at least a portion of an immunoglobulin constant region (Fc), typically that of a human

30 immunoglobulin (Jones *et al.*, 1986; Riechmann *et al.*, 1988; and Presta (1992) Curr. Op. Struct.

Biol., 2:593-596).

Human Antibodies

Fully human antibodies relate to antibody molecules in which essentially the entire
5   sequences of both the light chain and the heavy chain, including the CDRs, arise from human
genes. Such antibodies are termed "human antibodies", or "fully human antibodies" herein.
Human monoclonal antibodies can be prepared by the trioma technique; the human B-cell
hybridoma technique (see Kozbor, et al. (1983) Immunol Today 4: 72) and the EBV hybridoma
technique to produce human monoclonal antibodies (see Cole, et al., 1985 In: MONOCLONAL
10   ANTIBODIES AND CANCER THERAPY, Alan R. Liss, Inc., pp. 77-96). Human monoclonal
antibodies may be utilized in the practice of the invention and may be produced by using human
hybridomas (see Cote, et al. (1983) Proc Natl Acad Sci USA 80: 2026-2030) or by transforming
human B-cells with Epstein Barr Virus in vitro (see Cole, et al. (1985) In: MONOCLONAL
ANTIBODIES AND CANCER THERAPY, Alan R. Liss, Inc., pp. 77-96).
15   In addition, human antibodies can also be produced using additional techniques,
including phage display libraries. See Hoogenboom and Winter (1991) J. Mol. Biol., 227:381;
Marks et al. (1991) J. Mol. Biol., 222:581. Similarly, human antibodies can be made by
introducing human immunoglobulin loci into transgenic animals, e.g., mice in which the
endogenous immunoglobulin genes have been partially or completely inactivated. Upon
20   challenge, human antibody production is observed, which closely resembles that seen in humans
in all respects, including gene rearrangement, assembly, and antibody repertoire. This approach
is described, for example, in U.S. Patent Nos. 5,545,807; 5,545,806; 5,569,825; 5,625,126;
5,633,425; 5,661,016, and in Marks et al. (Bio/Technology 10, 779-783 (1992)); Lonberg et al.
(Nature 368 856-859 (1994)); Morrison (Nature 368, 812-13 (1994)); Fishwild et al., (Nature
25   Biotechnology 14, 845-51 (1996)); Neuberger (Nature Biotechnology 14, 826 (1996)); and
Lonberg and Huszar (Intern. Rev. Immunol. 13 65-93 (1995)).
Human antibodies may additionally be produced using transgenic nonhuman animals
which are modified so as to produce fully human antibodies rather than the animal's endogenous
antibodies in response to challenge by an antigen. See PCT publication WO94/02602. The
30   endogenous genes encoding the heavy and light immunoglobulin chains in the nonhuman host

have been incapacitated, and active loci encoding human heavy and light chain immunoglobulins are inserted into the host's genome. The human genes are incorporated, for example, using yeast artificial chromosomes containing the requisite human DNA segments. An animal which provides all the desired modifications is then obtained as progeny by crossbreeding intermediate

5   transgenic animals containing fewer than the full complement of the modifications. The preferred embodiment of such a nonhuman animal is a mouse, and is termed the Xenomouse™ as disclosed in PCT publications WO 96/33735 and WO 96/34096. This animal produces B cells which secrete fully human immunoglobulins. The antibodies can be obtained directly from the animal after immunization with an immunogen of interest, as, for example, a preparation of a

10   polyclonal antibody, or alternatively from immortalized B cells derived from the animal, such as hybridomas producing monoclonal antibodies. Additionally, the genes encoding the immunoglobulins with human variable regions can be recovered and expressed to obtain the antibodies directly, or can be further modified to obtain analogs of antibodies such as, for example, single chain Fv molecules.

15   An example of a method of producing a nonhuman host, exemplified as a mouse, lacking expression of an endogenous immunoglobulin heavy chain is disclosed in U.S. Patent No. 5,939,598. It can be obtained by a method including deleting the J segment genes from at least one endogenous heavy chain locus in an embryonic stem cell to prevent rearrangement of the locus and to prevent formation of a transcript of a rearranged immunoglobulin heavy chain locus,

20   the deletion being effected by a targeting vector containing a gene encoding a selectable marker; and producing from the embryonic stem cell a transgenic mouse whose somatic and germ cells contain the gene encoding the selectable marker.

A method for producing an antibody of interest, such as a human antibody, is disclosed in U.S. Patent No. 5,916,771. It includes introducing an expression vector that contains a

25   nucleotide sequence encoding a heavy chain into one mammalian host cell in culture, introducing an expression vector containing a nucleotide sequence encoding a light chain into another mammalian host cell, and fusing the two cells to form a hybrid cell. The hybrid cell expresses an antibody containing the heavy chain and the light chain.

In a further improvement on this procedure, a method for identifying a clinically relevant

30   epitope on an immunogen, and a correlative method for selecting an antibody that binds

immunospecifically to the relevant epitope with high affinity, are disclosed in PCT publication WO 99/53049.

Fab Fragments and Single Chain Antibodies

5   According to the invention, techniques can be adapted for the production of single-chain antibodies specific to an antigenic protein of the invention (see *e.g.*, U.S. Patent No. 4,946,778). In addition, methods can be adapted for the construction of Fab expression libraries (see *e.g.*, Huse, *et al.* (1989) Science 246: 1275-1281) to allow rapid and effective identification of monoclonal Fab fragments with the desired specificity for a protein or derivatives, fragments,

10   analogs or homologs thereof. Antibody fragments that contain the idiotypes to a protein antigen may be produced by techniques known in the art including, but not limited to: (i) an $F(ab')_2$ fragment produced by pepsin digestion of an antibody molecule; (ii) an Fab fragment generated by reducing the disulfide bridges of an $F(ab')_2$ fragment; (iii) an Fab fragment generated by the treatment of the antibody molecule with papain and a reducing agent and (iv) Fv fragments.

15

Bispecific Antibodies

Bispecific antibodies are monoclonal, preferably human or humanized, antibodies that have binding specificities for at least two different antigens. In the present case, one of the binding specificities is for an antigenic protein of the invention. The second binding target is any

20   other antigen, and advantageously is a cell-surface protein or receptor or receptor subunit.

Methods for making bispecific antibodies are known in the art. Traditionally, the recombinant production of bispecific antibodies is based on the co-expression of two immunoglobulin heavy-chain/light-chain pairs, where the two heavy chains have different specificities. (Milstein and Cuello (1983) Nature, 305:537-539. Because of the random

25   assortment of immunoglobulin heavy and light chains, these hybridomas (quadromas) produce a potential mixture of ten different antibody molecules, of which only one has the correct bispecific structure. The purification of the correct molecule is usually accomplished by affinity chromatography steps. Similar procedures are disclosed in WO 93/08829, and in Traunecker *et al.* (1991) *EMBO J.*, 10:3655-3659.

30   Antibody variable domains with the desired binding specificities (antibody-antigen

combining sites) can be fused to immunoglobulin constant domain sequences. The fusion preferably is with an immunoglobulin heavy-chain constant domain, comprising at least part of the hinge, CH2, and CH3 regions. It is preferred to have the first heavy-chain constant region (CH1) containing the site necessary for light-chain binding present in at least one of the fusions.

5   DNAs encoding the immunoglobulin heavy-chain fusions and, if desired, the immunoglobulin light chain, are inserted into separate expression vectors, and are co-transfected into a suitable host organism. For further details of generating bispecific antibodies see, for example, Suresh *et al.* (1986) Methods in Enzymology, 121:210.

According to another approach described in WO 96/27011, the interface between a pair
10   of antibody molecules can be engineered to maximize the percentage of heterodimers which are recovered from recombinant cell culture. The preferred interface comprises at least a part of the CH3 region of an antibody constant domain. In this method, one or more small amino acid side chains from the interface of the first antibody molecule are replaced with larger side chains (*e.g.* tyrosine or tryptophan). Compensatory "cavities" of identical or similar size to the large side
15   chain(s) are created on the interface of the second antibody molecule by replacing large amino acid side chains with smaller ones (*e.g.* alanine or threonine). This provides a mechanism for increasing the yield of the heterodimer over other unwanted end-products such as homodimers.

Bispecific antibodies can be prepared as full length antibodies or antibody fragments (*e.g.* $F(ab')_2$ bispecific antibodies). Techniques for generating bispecific antibodies from antibody
20   fragments have been described in the literature. For example, bispecific antibodies can be prepared using chemical linkage. Brennan *et al.* (1985) Science 229:81 describe a procedure wherein intact antibodies are proteolytically cleaved to generate $F(ab')_2$ fragments. These fragments are reduced in the presence of the dithiol complexing agent sodium arsenite to stabilize vicinal dithiols and prevent intermolecular disulfide formation. The Fab' fragments
25   generated are then converted to thionitrobenzoate (TNB) derivatives. One of the Fab'-TNB derivatives is then reconverted to the Fab'-thiol by reduction with mercaptoethylamine and is mixed with an equimolar amount of the other Fab'-TNB derivative to form the bispecific antibody. The bispecific antibodies produced can be used as agents for the selective immobilization of enzymes.

30   Additionally, Fab' fragments can be directly recovered from E. coli and chemically

31

coupled to form bispecific antibodies. Shalaby *et al.* (1992) J. Exp. Med. 175:217-225 describe

the production of a fully humanized bispecific antibody F(ab')$_2$ molecule. Each Fab' fragment

was separately secreted from E. coli and subjected to directed chemical coupling *in vitro* to form

the bispecific antibody. The bispecific antibody thus formed was able to bind to cells

5   overexpressing the ErbB2 receptor and normal human T cells, as well as trigger the lytic activity

of human cytotoxic lymphocytes against human breast tumor targets.

Various techniques for making and isolating bispecific antibody fragments directly from

recombinant cell culture have also been described. For example, bispecific antibodies have been

produced using leucine zippers. Kostelny *et al.* (1992) J. Immunol. 148(5):1547-1553. The

10   leucine zipper peptides from the Fos and Jun proteins were linked to the Fab' portions of two

different antibodies by gene fusion. The antibody homodimers were reduced at the hinge region

to form monomers and then re-oxidized to form the antibody heterodimers. This method can

also be utilized for the production of antibody homodimers. The "diabody" technology described

by Hollinger *et al.* (1993) Proc. Natl. Acad. Sci. USA 90:6444-6448 has provided an alternative

15   mechanism for making bispecific antibody fragments. The fragments comprise a heavy-chain

variable domain (V_H) connected to a light-chain variable domain (V_L) by a linker which is too

short to allow pairing between the two domains on the same chain. Accordingly, the V_H and V_L

domains of one fragment are forced to pair with the complementary V_L and V_H domains of

another fragment, thereby forming two antigen-binding sites. Another strategy for making

20   bispecific antibody fragments by the use of single-chain Fv (sFv) dimers has also been reported.

See, Gruber *et al.* (1994) J. Immunol. 152:5368.

Antibodies with more than two valencies are contemplated. For example, trispecific

antibodies can be prepared. Tutt *et al.* (1991) J. Immunol. 147:60.

Exemplary bispecific antibodies can bind to two different epitopes, at least one of which

25   originates in the protein antigen of the invention. Alternatively, an anti-antigenic arm of an

immunoglobulin molecule can be combined with an arm which binds to a triggering molecule on

a leukocyte such as a T-cell receptor molecule (*e.g.* CD2, CD3, CD28, or B7), or Fc receptors for

IgG (Fc R), such as Fc RI (CD64), Fc RII (CD32) and Fc RIII (CD16) so as to focus cellular

defense mechanisms to the cell expressing the particular antigen. Bispecific antibodies can also

30   be used to direct cytotoxic agents to cells which express a particular antigen. These antibodies

possess an antigen-binding arm and an arm which binds a cytotoxic agent or a radionuclide chelator, such as EOTUBE, DPTA, DOTA, or TETA. Another bispecific antibody of interest binds the protein antigen described herein and further binds tissue factor (TF).

5   Pharmaceutical Compositions

The IL-21 modulators described herein can be conveniently provided in pharmaceutical compositions. The compositions are preferably suitable for internal use and include an effective amount of a pharmacologically active compound of the invention, alone or in combination, with one or more pharmaceutically acceptable carriers. The compounds are especially useful in that 10   they have very low, if any toxicity.

In practice, the compounds or their pharmaceutically acceptable salts, are administered in amounts which will be sufficient to effect the desired change, i.e., an increase or decrease in IL-21 levels, and are used in the pharmaceutical form most suitable for such purposes.

For instance, for oral administration in the form of a tablet or capsule (*e.g.*, a gelatin 15   capsule), the active drug component can be combined with an oral, non-toxic pharmaceutically acceptable inert carrier such as ethanol, glycerol, water and the like. Moreover, when desired or necessary, suitable binders, lubricants, disintegrating agents and coloring agents can also be incorporated into the mixture. Suitable binders include starch, magnesium aluminum silicate, starch paste, gelatin, methylcellulose, sodium carboxymethylcellulose and/or 20   polyvinylpyrrolidone, natural sugars such as glucose or beta-lactose, corn sweeteners, natural and synthetic gums such as acacia, tragacanth or sodium alginate, polyethylene glycol, waxes and the like. Lubricants used in these dosage forms include sodium oleate, sodium stearate, magnesium stearate, sodium benzoate, sodium acetate, sodium chloride, silica, talcum, stearic acid, its magnesium or calcium salt and/or polyethyleneglycol and the like. Disintegrators include, 25   without limitation, starch, methyl cellulose, agar, bentonite, xanthan gum starches, agar, alginic acid or its sodium salt, or effervescent mixtures, and the like. Diluents, include, *e.g.*, lactose, dextrose, sucrose, mannitol, sorbitol, cellulose and/or glycine.

Injectable compositions are preferably aqueous isotonic solutions or suspensions, and suppositories are advantageously prepared from fatty emulsions or suspensions. The 30   compositions may be sterilized and/or contain adjuvants, such as preserving, stabilizing, wetting

33

or emulsifying agents, solution promoters, salts for regulating the osmotic pressure and/or buffers. In addition, they may also contain other therapeutically valuable substances. The compositions are prepared according to conventional mixing, granulating or coating methods, respectively, and contain about 0.1 to 75%, preferably about 1 to 50%, of the active ingredient.

5   The compounds of the invention can also be administered in such oral dosage forms as timed release and sustained release tablets or capsules, pills, powders, granules, elixers, tinctures, suspensions, syrups and emulsions.

   Liquid, particularly injectable compositions can, for example, be prepared by dissolving, dispersing, etc. The active compound is dissolved in or mixed with a pharmaceutically pure

10 solvent such as, for example, water, saline, aqueous dextrose, glycerol, ethanol, and the like, to thereby form the injectable solution or suspension. Additionally, solid forms suitable for dissolving in liquid prior to injection can be formulated. Injectable compositions are preferably aqueous isotonic solutions or suspensions. The compositions may be sterilized and/or contain adjuvants, such as preserving, stabilizing, wetting or emulsifying agents, solution promoters,

15 salts for regulating the osmotic pressure and/or buffers. In addition, they may also contain other therapeutically valuable substances.

   The compounds of the invention can be administered in intravenous (both bolus and infusion), intraperitoneal, subcutaneous or intramuscular form, all using forms well known to those of ordinary skill in the pharmaceutical arts. Injectables can be prepared in conventional

20 forms, either as liquid solutions or suspensions.

   Parenteral injectable administration is generally used for subcutaneous, intramuscular or intravenous injections and infusions. Additionally, one approach for parenteral administration employs the implantation of a slow-release or sustained-released systems, which assures that a constant level of dosage is maintained, according to U.S. Pat. No. 3,710,795, incorporated herein

25 by reference.

   Furthermore, preferred compounds for the invention can be administered in intranasal form via topical use of suitable intranasal vehicles, or via transdermal routes, using those forms of transdermal skin patches well known to those of ordinary skill in that art. To be administered in the form of a transdermal delivery system, the dosage administration will, of course, be

30 continuous rather than intermittent throughout the dosage regimen. Other preferred topical

34

preparations include creams, ointments, lotions, aerosol sprays and gels, wherein the concentration of active ingredient would range from 0.1% to 15%, w/w or w/v.

For solid compositions, excipients include pharmaceutical grades of mannitol, lactose, starch, magnesium stearate, sodium saccharin, talcum, cellulose, glucose, sucrose, magnesium

5   carbonate, and the like may be used. The active compound defined above, may be also formulated as suppositories using for example, polyalkylene glycols, for example, propylene glycol, as the carrier. In some embodiments, suppositories are advantageously prepared from fatty emulsions or suspensions.

The compounds of the invention can also be administered in the form of liposome

10   delivery systems, such as small unilamellar vesicles, large unilamellar vesicles and multilamellar vesicles. Liposomes can be formed from a variety of phospholipids, containing cholesterol, stearylamine or phosphatidylcholines. In some embodiments, a film of lipid components is hydrated with an aqueous solution of drug to a form lipid layer encapsulating the drug, as described in U.S. Pat. No. 5,262,564.

15   Compounds of the invention may also be delivered by the use of monoclonal antibodies as individual carriers to which the compound molecules are coupled. The compounds of the invention may also be coupled with soluble polymers as targetable drug carriers. Such polymers can include polyvinylpyrrolidone, pyran copolymer, polyhydroxypropyl-methacrylamide-phenol, polyhydroxyethylaspanamidephenol, or polyethyleneoxidepolylysine substituted with palmitoyl

20   residues. Furthermore, the compounds of the invention may be coupled to a class of biodegradable polymers useful in achieving controlled release of a drug, for example, polylactic acid, polyepsilon caprolactone, polyhydroxy butyric acid, polyorthoesters, polyacetals, polydihydropyrans, polycyanoacrylates and cross-linked or amphipathic block copolymers of hydrogels.

25   The nucleic acid molecules of the invention can be inserted into vectors and used as gene therapy vectors. Gene therapy vectors can be delivered to a subject by, for example, intravenous injection, local administration (*see, e.g.,* U.S. Patent No. 5,328,470) or by stereotactic injection (*see, e.g.,* Chen, *et al.,* 1994. *Proc. Natl. Acad. Sci. USA* 91: 3054-3057). Pharmaceutical preparation of the gene therapy vector can include the gene therapy vector in an acceptable

30   diluent, or can comprise a slow release matrix in which the gene delivery vehicle is imbedded.

Alternatively, where the complete gene delivery vector can be produced intact from recombinant cells, *e.g.*, retroviral vectors, the pharmaceutical preparation can include one or more cells that produce the gene delivery system.

5   If desired, the pharmaceutical composition to be administered may also contain minor amounts of non-toxic auxiliary substances such as wetting or emulsifying agents, pH buffering agents, and other substances such as for example, sodium acetate, triethanolamine oleate, etc.

The dosage regimen utilizing the compounds is selected in accordance with a variety of factors including type, species, age, weight, sex and medical condition of the patient; the severity of the condition to be treated; the route of administration; the renal and hepatic function of the

10   patient; and the particular compound or salt thereof employed. An ordinarily skilled physician or veterinarian can readily determine and prescribe the effective amount of the drug required to prevent, counter or arrest the progress of the condition.

Oral dosages of the invention, when used for the indicated effects, will range between about 0.05 to 1000 mg/day orally. The compositions are preferably provided in the form of

15   scored tablets containing 0.5, 1.0, 2.5, 5.0, 10.0, 15.0, 25.0, 50.0, 100.0, 250.0, 500.0 and 1000.0 mg of active ingredient. Effective plasma levels of the compounds of the invention range from 0.002 mg to 50 mg per kg of body weight per day.

Compounds of the invention may be administered in a single daily dose, or the total daily dosage may be administered in divided doses of two, three or four times daily.

20   Any of the above pharmaceutical compositions may contain 0.1-99%, preferably 1-70% of the IL-21, IL-21 receptor, IL-21 agonist, or IL-21 antagonist.

If desired, the pharmaceutical compositions can be provided with an adjuvant. Adjuvants are discussed above. In some embodiments, adjuvants can be used to increase the immunological response, depending on the host species, include Freund's (complete and

25   incomplete), mineral gels such as aluminum hydroxide, surface active substances such as lysolecithin, pluronic polyols, polyanions, peptides, oil emulsions, keyhole limpet hemocyanin, dinitrophenol, and potentially useful human adjuvants such as BCG (bacille Calmette-Guerin) and Corynebacterium parvum. Generally, animals are injected with antigen using several injections in a series, preferably including at least three booster injections.

36

The invention will be further illustrated in the following non-limiting examples. Examples 1-8 were performed using the following materials and methods.

EXAMPLES

5 **Mice**

Unless indicated otherwise, C57BL/6 mice of 6-8 weeks of age were used in all experiments. Stat6-deficient mice on C57BL/6-deficient background were generated as described in Kaplan, M.H., et al., Immunity 4: 313-9, 1996.

10 **Lymphocyte preparation and culture**

Lymphocytes were cultured in RPMI 1640 supplemented as described in (Kaplan, M.H., et al., Immunity 4: 313-9, 1996). Naïve Thp cells were purified from lymph node and spleens by cell sorting using anti-CD4 and anti-CD26L (Pharmingen; BD Life Sciences, San Diego, CA) to 15 95-98% purity.

Antibodies and cytokines

T-bet specific antiserum was prepared as described in (Szabo, S.J. et al., Cell 100: 655-20 69, 2000). Antibodies specific for Stat4, Stat1, and actin were obtained from Santa Cruz Biotechnology (Santa Cruz, CA). An antibody specific for phosphorylated Stat4 was obtained from Zymed (South San Francisco, CA). The antibodies to anti-CD3, and-CD28, IL-4, and IFNγ used in Th differentiation cultures were obtained from Pharmingen. Recombinant IL-4 was obtained from Preprotech. Recombinant IL-2 was provided by Chiron (Emeryville, CA). 25 Recombinant IL-12 was provided by Hoffman-LaRoche (Nutley, NJ). Mouse IL-21 expressed in COS supernatants was prepared and concentrated. One unit of activity was defined as the concentration of supernatent required to induce 50% maximal proliferation of BAF3 cells transfected with IL-21R. Mock transfected COS supernatent, prepared and concentrated in parallel with IL-21, was used as a control.

30

In vitro T helper cell differentiation

      Naïve T cells were plated onto anti-CD3, anti-CD28 (1μg/ml) coated plates at 1-2 X 10^6/ml in the presence of 10 ng/ml IL-4, 10 μg/ml anti-IFNγ (Th2 conditions) or 1 ng/ml IL-12, 10μg/ml anti IL-4 (Th1 conditions). Cells were expanded in IL-2 (100 U/ml) three days later.

5   After one week in culture, the cells were stimulated with PMA/Ionomycin, and cytokine production was determined by intracellular cytokine staining as described in (Bird, J.J. et al., Immunity 9: 229-37, 1998).

RNA Analysis

10   Total RNA was isolated using RNeasy (Qiagen; Valencia, CA). For northern analysis, the RNA was separated on a 1.5% agarose/6% formaldehyde gel and transferred to GeneScreen membrane (New England Nuclear). The membrane was hybridized with radiolabeled cDNA probes for IL-21, Il-4, IFNγ, γ-actin. For RealTime PCR, 1μg of RNA was primed with oligo (dT) and converted to cDNA using Superscript (Invitrogen Life Technologies; Carlsbad, CA). 25

15   ng of cDNA was used as template in PCR reations using SYBR Green 2X or TaqMan 2X PCR mix (Applied Biosystems; Foster City, CA) and analyzed in the ABI Prism 7700 Sequence Detector (Applied Biosystems) using the following primers:

Il-21 forward; 5'aagattcctgaggatccgagaag-3' (SEQ ID NO:7)

IL-21 reverse: 5'gcattcgtgagcgtctatagtgtc-3' (SEQ ID NO:8)

20   IL-21 TaqMan probe: 5'ttcccgaggactgaggagacgcc-3' (SEQ ID NO:9)

IL-12Rγ2 forward: 5'tttccatttttgcatcaagttctc3' (SEQ ID NO:10)

IL-12Rγ2 reverse: 5'ccgatctagagtcagccgct 3' (SEQ ID NO:11)

Stat4 forward: 5'aaacctgagcccaacgacaa3' (SEQ ID NO:12)

Stat4 reverse: 5'agtgtccgtttgcaccgtc3' (SEQ ID NO:13)

25   Primers and TaqMan probes for IL-4, IFNγ, and GAPDH have been published previously (Overbergh, L., et al., Cytokine 11: 305-12 1999).

Immunoblot analysis

      Whole cell extracts were prepared by lysing cells in 50 mM Tris, 0.5% NP40, 5 mM

30   EDTA, 50 mM NaCl and clearing the lysates by centrifugation. Protein extracts were separated

on an 8-10% polyacrylamide gel and transferred to an Optitran membrane (Schleicher and Schuell; Keene, NH). The immunoblots were blocked for one hour at room temperature in 5% milk in TBST (50 mM Tris Ph 7.5, 100mM NaCl, 0.03% Tween 20) and incubated with the indicated antibody overnight at 4 degrees Centigrade. The blots were washed with TBST and

5   incubated with anti-rabbit HRP-conjuguated antibody (Zymed) at room temperature. After washing the blots with TBST, detection was performed using enhanced chemiluminescence (Amersham; Piscataway,NJ) according to the manufacturer's instructions.

Example 1. IL-21 is preferentially expressed in Th cells induced to develop along Th2

10   **pathway *in vitro*.**

Expression of IL-21 in Th subsets was determined. Northern analysis was performed on mRNA from naïve Thp (Th precursor) cells differentiated into Th1 or Th2 cells for one week and restimulated for four hours to induce cytokine production. The results are shown in FIGS. 1A-1D. For the results shown in FIG. 1A, Thp cells were cultured under Th1 and Th2 skewing

15   conditions for 6 days. The cells were left resting (-) or restimulated with PMA/Ionomycin (P+I) for 4 hours. RNA was purified and assessed for cytokine expression by Northern blot. The results shown are representative of three independent experiments. Message encoding IL-21 was detected only in stimulated Th2 cells, and in contrast IL-21 message was undetectable in Th1 cultures. These results indicate that IL-21 is a Th2-specific cytokine.

20   To determine whether the potential to express IL-21 increases as cells develop along a Th2 pathway, IL-21 expression in primary stimulated Thp cells was compared to Il-21 message expression in secondary stimulated Th2 cells. The results are shown in FIG. 1B. For the results shown, Thp cells were cultured under neutral, Th1 and Th2 skewing conditions. RNA was purified 24 hours after primary and secondary anti-CD3 stimulation. Cytokine expression was

25   assessed in duplicate by RealTime PCR and shown relative to GAPDH. IL-21 message, like IL-4, was observed to be relatively low in Thp cells after primary stimulation. In contrast, Il-21 expression was markedly increased after cells were allowed to differentiate along the Th2 pathway. These results demonstrate that Il-21 gene expression is regulated similarly to other Th2-specific cytokines.

The effect of cytokine milieu on IL-21 expression in differentiated cells was determined. Th1 and Th2 cells were cultured in the presence of IL-4 and IFNγ, respectively, before secondary stimulation. Cells were responsive to these cytokines as evidenced by the activation of Stat6 and Stat1 by IL-4 and IFNγ.

5   The ability of IL-4 to restore IL-21 expression was examined. The results are shown in FIG. 1C. Thp cells were cultured under Th1 and Th2 skewing conditions for 5 days. IL-4 or IFNγ were added to indicated cultures 24 hours prior to secondary stimulation with anti-CD3. RNA was purified 24 hours after secondary stimulation and IL-21 expression was assessed in duplicate relative to GAPDH by RealTime PCR. Addition of IL-4 to Th1 cells was not able to

10   restore IL-21 expression to the level seen in Th2 cells. Moreover, the addition of IFNγ to the Th2 cultures had no inhibitory effect on the expression of IL-21. These results demonstrate that expression of IL-21 in Th2 cells appears to be fixed early in Th2 differentiation and is not modulated directly by IL-4 or IFNγ.

15   **Example 2. Th2 cells express IL-21 during a Th2 immune response in vivo.**

The expression of IL-21 in Th2 cells during an in vivo immune response was determined in a pathogenic protozoan model system. Infection with the protozoan *Leishmania major* provides a well-characterized model for studying the *in vivo* response of Th cells (Reiner, S.L., et al., Annu Rev Immunol 13: 151-77, 1995). Some inbred mouse strains, such as C57BL/6,

20   infected with *L. major* mount a protective and effective Th1 response against the pathogen. Conversely, other inbred mouse strains, such as BALB mouse strains, develop primarily a Th2 response and fail to clear the infection.

Both C57BL/6 and BALB/c mice were infected with *L. major*. Cohorts of 8 BALB/c and C57BL/6 mice were infected with L. *major* in hind footpads. After 6 weeks CD4+ T cells from

25   draining lymph nodes were purified and stimulated with anti-CD3. RNA was purified 6 hours after stimulation and cytokine expression was assessed relative to GAPDH by RealTime PCR.

The results are shown in FIG. 1D. As expected, CD4+ cells from C57BL/6 infected mice expressed more IFNγ than cells from BALB/c infected mice. Consistent with a predominantly Th2 response, CD4+ T cells from infected BALB/c mice made significantly more IL-4 than T

30   cells from C57BL/6 mice. Similar to what was observed under in vitro Th2 skewing conditions,

IL-21 was also preferentially expressed during an in vivo Th2 response in BALB/c mice. These results, combined with *in vitro* findings (Example 1), demonstrate that IL-21 is a Th2 cytokine.

Example 3. IL-21 specifically inhibits production of IFNγ in developing Th cells.

5   Because IL-21 shares a similar expression profile in Th cells as well as structural similarity to IL-4, the ability of IL-21, like IL-4, to influence Th differentiation directly was determined.

To determine the effect of IL-21 on Thp differentiation, Thp cells were cultured under neutral, Th1 and Th2 skewing conditions.

10   Purified naïve Thp cells were primed under neutral, Th1, and Th2 skewing conditions in the presence and absence of IL-21. The cytokine potential of these cells was assessed by intracellular cytokine staining after one week in culture.

The results are shown in FIGS. 2A and 2B. For the results shown in FIG. 2A, cells were cultured for one week in the presence of IL-21 or mock supernatants. Cytokine production was

15   assessed by intracellular cytokine staining four hours after restimulation with PMA/Ionomycin. Results are representative of at least ten experiments.

As with IL-4, addition of IL-21 to neutral and Th1 cultures resulted in a marked reduction in the number of IFNγ producing cells (FIG. 2A, neutral and Th1 conditions). The decreased number of IFNγ producing cells in Th1 cultures was confirmed by ELISPOT analysis. However,

20   unlike what was observed with IL-4, IL-21 by itself was unable to potentiate the production of IL-4 producing Th2 cells (FIG. 2A, neutral condition). IL-21 treatment had no stimulating or inhibitory effect on the generation of IL-4 producing cells under Th2 skewing conditions (FIG. 2A, Th2).

The ability of IL-21 to affect IFNγ production from recently stimulated Thp cells was

25   determined. Purified naïve Thp cells were cultured under neutral and Th1 conditions in the presence or absence of IL-21 for 48 hours. The resulting culture supernatants were examined for IFNγ production using ELISA. It was found that IL-21 reduced the amount of IFNγ produced early in differentiating cultures (FIG. 2B). Therefore, the presence of IL-21 during Th priming affects the ability of both differentiating Th1 cells and effector cells to produce IFNγ.

30

Example 4. IL-21 does not directly inhibit IFNγ production from Th1 effector cells.

To determine whether IL-21 directly represses production of IL-21, or instead affects differentiation of IFNγ cells, purified naïve Thp cells were cultured under Th1 skewing conditions. IL-21 or mock supernatant was added either at the beginning of culture (Day 0) or 24

5   hours before restimulation and analysis (Day 5). Cytokine production was assessed by intracellular cytokine staining. The results are shown in FIG. 3A.

Unlike what was observed when IL-21 was added at Day 0, the addition of IL-21 to Th1 cultures at the end of the differentiation period had no effect on IFNγ production, even though Th1 cells express IL-21R and are responsive to IL-21. This finding demonstrates the IL-21

10   impairs the ability of Thp cell differentiation into IFNγ-producing Th1 cells, but does not directly inhibit IFNγ production from Th1 effector cells.

Example 5. IL-21 inhibition of IFNγ is independent of Stat6.

The ability of IL-4 to inhibit the differentiation of Th1 cells depends on the expression of

15   Stat6 (Kaplan, M.H., et al., Immunity 4: 313-9, 1996, Takeda, K. et al., Nature 380: 627-30 1996, and Shimoda, K. et al., Nature 380: 630-3, 1996).

In order to determine whether IL-21 mediated inhibition of IFNγ production is also dependent on Stat6, the ability of IL-21 to influence Th1 differentiation in cells lacking Stat6 was determined. Thp cells purified from wild-type or Stat6-deficient mice were cultured for one

20   week under Th1 skewing conditions in the presence of IL-21 or mock supernatant. Cytokine production was assessed by intracellular cytokine staining.

The results are shown in FIG. 3B. In the absence of Stat6, IL-21 was just as effective in preventing the generation of IFNγ producing cells as in the presence of Stat6. Therefore, unlike IL-4, IL-21 does not depend on Stat6 signaling to prevent the generation of IFNγ producing Th1

25   cells. Additionally, these results demonstrate that the repression of IFNγ induced by IL-21 is not mediated directly through the action of IL-4.

Example 6. IL-21 does not inhibit other Th1 cytokines

To determine if IL-21 affects aspects of Th1 development in addition to inhibition of IFNγ production, the ability of IL-21 treated Th1 cells to produce other Th1-associated cytokines was examined.

Thp cells were cultured under Th1 skewing conditions in the presence of IL-21, or of mock supernatants, after which they were assessed for cytokine production by intracellular cytokine staining after secondary stimulation.

The results are shown in FIG. 3C. Surprisingly, although the number of IFNγ producing cells is significantly reduced when IL-21 is included in the priming conditions, the same cell population had normal numbers of IL-2 and TNFα producing cells. These results demonstrate that that although IL-21 efficiently suppresses the ability of Th1 cells to produce IFNγ, the same cells maintain the capacity to produce Th1 cells and do not default to produce Th2 cytokines.

Example 7. T-bet expression is unaffected by IL-21

T-bet is a recently identified transcription factor that is specifically expressed in differentiating Th1 cells and which is also capable of potently inducing IFNγ. To determine if IL-21 treatment of differentiating Th1 cells affected the induction of T-bet expression in Th cells, Thp cells were cultured under Th1 or Th2 skewing conditions. Protein extracts were harvested at the beginning (naïve) and 48 hours after culture (Th1 and Th2). T-bet and actin expression were determined by western blot.

The results are shown in FIG. 4A. IL-21 or mock supernatants were included in the indicated cultures. As expected, T-bet expression was induced in Th1 cultures and remained low under Th2 conditions. Addition of IL-21 had no effect on T-bet expression in Th1 cells. This result indicates that IL-21-mdiated expression of IFNγ expression is not a result of reduced T-bet expression.

Example 8. IL-21 inhibits IL-12 signaling.

IL-12 signaling is reported to play an important role in the development of Th1 cells. Th cells lacking IL-12R are severely compromised in their ability to produce IFNγ (Wu, C., et al., J Immunol 159: 1658-65, 1997). Additionally, IL-12Rβ2 chain expression is specifically extinguished in developing Th2 cells, an effect mediated by IL-4 (Szabo, S.J., et al., J Exp Med

185: 817-24, 1997). In order to determine if IL-21, like IL-4, affects the expression of IL-12b2 chain in Th1 cells, RNA from naïve Thp cells cultured under Th1 and Th2 skewing conditions in the presence and absence of IL-21 was analyzed for 12Rβ2 expression by RealTime PCR. Thp cells were cultured under Th 1 or Th2 skewing conditions for one week. IL-21 or mock

5   supernatant was included in indicated cultures. RNA was harvested 24 hours after secondary stimulation with anti-CD3 and assessed for IL-l2Rβ2 expression by RealTime PCR.

The results are shown in FIG. 4B. The results are representative of three independent experiments. As expected, IL-12Rβ2expression was high in Th1 cells when compared to Th2 cells. However, addition of IL-21 to the Th1 cultures did not affect IL-12Rβ2 expression.

10   Therefore, unlike results reported for IL-4, IL-21 did not cause decreased expression of IL-12Rβ2. Moreover, the high IL-12Rβ2 expression coupled with high TNFα and IL-2 levels suggest that IL-21 treated Th1 cells maintain many Th1 characteristics with the distinct exception of decreased IFNγ production.

Stat4 is specifically activated by IL-12 and is reported to be a critical mediator for the

15   generation of IFNγ producing Th1 cells (Wurster, A.L., et al., Oncogene 19: 2577-84, 2000). In order to determine if IL-21 affects the ability of IL-12 to activate STAT-4, naïve Thp cells were activated for 48 hours in the presence or absence of IL-21. The cells were subsequently stimulated with IL-12, and the extent of Stat4 phosphorylation was determined by western blot analysis. Thp cells were stimulated with anti-CD3 for 48 hours in the presence of IL-21 or mock

20   supernatants. Protein extracts were assessed for phosphorylated Stat4 (p-Stat4), Stat4 and Statl by western blot. Results are representative of four independent experiments.

The results are shown in FIG. 4C. Although IL-21 treated cells were found to express normal levels of IL-12Rβ2, Stat4 phosphorylation in response to IL-12 stimulation was reduced in IL-21 treated cells. The decreased levels of phosphorylated Stat4 is also reflected by a

25   decrease in total Stat4 protein levels. As a comparison, Stat1 protein was unaffected by IL-21 treatment.

Stat4 RNA levels were also examined. Thp cells were cultured as described for FIG. 4C, after which RNA was harvested and assessed for Stat4 expression in duplicate by RealTime PCR.

The results are shown in FIG. 4D. Results are representative of three independent experiments. Lower levels of Stat4 RNA levels were detected. The IL-21 induced decrease in Stat4 protein levels is likely due to a decrease in Stat4 mRNA. These findings suggest that IL-21 hinders the responsiveness of developing Th1 cells to IL-12 through a reduction of Stat4 gene

5   expression.

Example 9. IL-21 signaling is required for limiting a Th1 response in vivo.

To determine if endogenously produced IL-21 plays a role in limiting Th1 cell function in vivo, the extent of delayed-type hypersensitivity response (DTH) was examined in IL-21R-

10   deficient mice. DTH is a classic Th1 cell-mediated inflammatory response. IL-21R-deficient mice backcrossed on the C57BL/6 background were generated as described in Kasian et al., Immunity 16:559-60, 2002. Eight week old male mice were immunized subcutaneously with 100mg TNP-KLH (2,4,6-trinitrophenyl-keyhole limpet hemocyanin; Biosearch Technologies, Novato, CA) emulsified in DFA at the tail base. After six days mice were challenged with 50 μg

15   of TNP-KLH in one hind footpad and PBS in the contralateral hind footpad. Footpad thickness was measured 24 hours after challenge.

The results are presented in FIG. 5A. Specific footpad swelling of wild type and IL-21R-deficient (IL-21R-/-) mice was determined by subtracting nonspecific swelling the PBS-injected footpad from TNP-KLH-induced swelling. Each data point represents one mouse. Horizontal

20   lines indicate averages. Results reflect pooling of data from two independent experiments. The results demonstrate that wild type animals responded to antigenic challenge with robust swelling of the footpad. Surprisingly, IL-21R-deficient mice mounted a much stronger DTH response, resulting in an average of twice the swelling.

IFNγ production was also examined in immunized mice. The results are shown in FIG.

25   5B. Purified CD4+ T cells from draining lymph nodes of immunized mice were stimulated in vitro with 250 mg/ml TNP-KLH. Supernatants were analyzed for IFNγ levels by ELISA. Results shown are the average of data from two mice from each genotype performed in duplicate. The increased DTH response in IL-21R-deficient animals correlated with a marked increase in IFNγ production from CD4+ cells purified from the draining lymph nodes and restimulated by antigen

30   in vitro.

These results demonstrate that IL-21 is involved in limiting TH1 cell responses by suppressing the production of IFNγ.

Additional embodiments are within the claims.

5
